Abstract

Background: Currently, obesity affects almost a third of the world’s population. Traditionally, anthropometric measures such as waist circumference or body mass index (BMI) were used to quantify total obesity. The aim of this study was to estimate the relationship between Overweight BMI and Regular Exercise in Secondary School Students in Tikrit City. Patients and methods: This was a cross-sectional descriptive epidemiological study carried out to estimate the relationship between Overweight BMI and Regular Exercise in Secondary School Students in Tikrit City among 153 students (80 girls and 73 boys) and study the relationship between them. Results: In this study, male who doing exercise 1-2 times weekly was 44.83% less than non-doing as percentage 55.17%. In female, 11/23 (47.83%) do exercise 1-2 times weekly, while in male 13/29 (44.83%) do exercise 1-2 times weekly, as well as 8/23 (34.78%) from female do exercise 3-4 times weekly, while 9/29 (30.03%) in male do exercise regularly. In male, 7/29 (24.14%) do exercise more than 4 times weekly, while 4/23 (17.39%) from female do exercise more than 4 times weekly. In female, 16/23 (69.57%) do exercise for 0-30 mins, while in male 15/29 (51.72%) do exercise for 0-30 mins. In male, 8/29 (27.59%) do exercise for more than 60 mins, while 16/49 (32.66%) had an overweight BMI and 22/49 (44.9%) had central obesity. Conclusion: Most of the students have a normal BMI and a normal waist-to-height ratio and among secondary school students (34%) only have regular exercise, from them (46.15%) doing exercise 1-2 times weekly.

Keywords: Overweight; BMI; regular exercise; secondary school students; Tikrit city

Introduction

The obesity and overweight prevalence in both children and adolescents is considered as a pandemic problem worldwide (1). By participating in regular exercise programs, it is estimated that about approximately (22.0 million) overweight and obese people worldwide may be reduced (1), and according to WHO about three hundred million are defined as obese (BMI >30kg/m²) and one billion are overweight (BMI >25kg/m²) (2).

Obesity is caused by an imbalance in the consumption of calories that derive from food comparing to the expenditures via exercise and body activity (1). About 5% of the world’s deaths caused by overweight and obesity, so the physical inactivity is considered as fourth leading risk factor for mortality in the world and (6%) of deaths globally (3), as well as low movement behavior, there are indications of a significant increase in youth with weight-related concerns and an increased negative body image as adolescents progress (4).

Exercise recipes for obese people follow the same framework for the condition; intensity; forever; and the frequency has been explained. The amount of exercise which needed to lose weight is too large to be increased (5).

Patients and Methods

Cross-sectional study was used to assess Overweight BMI with and without regular exercise in secondary school students in Tikrit city, collected 153 cases of both gender from secondary school students (Ibn-almotam, Al-Khansaa and Al-Mustansrya), during the 1st of November to the 1st of January.

Finding

In figure-1 illustrates that male who doing exercise 1-2 times weekly 44.83% less than non-doing as percentage 55.17%.
Figure (1): Illustrates secondary school student (male gender) who are doing regular exercise weekly.

Figure (2): Illustrates secondary school student (female gender) who are doing regular exercise weekly.

Figure (3): Illustrates secondary school student (both gender) with their percent of how many times they do exercise weekly.
This figure illustrates that 11/23 (47.83%) from female do exercise 1-2 times weekly, while in male 13/29 (44.83%) do exercise 1-2 times weekly.

Also 8/23 (34.78%) from female do exercise 3-4 times weekly, while 9/29 (30.03%) in male do exercise regularly, In male 7/29 (24.14%) do exercise more than 4 times weekly, while 4/23 (17.39%) from female do exercise more than 4 times weekly.

![Bar chart showing exercise frequency by gender](chart.png)

Figure (4): Illustrates secondary school student (both gender) with their percent of duration taken to complete exercise.

This figure illustrates that female 16/23 (69.57%) do exercise for 0-30 mins, while in male 15/29 (51.72%) do exercise for 0-30 mins. Also 7/23 (30.43%) from female do exercise for 30-60 mins, while 6/29 (20.69%) in male do exercise for 30-60 mins. In male 8/29 (27.59%) do exercise for more than 60 mins.

![Bar chart showing duration of exercise](chart.png)

Figure (5): Illustrates secondary school student (both gender) with their percent of daily drinking glasses of water.

This figure shows that 48/80 (60%) of females drinking less than 4 glasses of water, while in male 39/73 (53.42%)

This table shows that 22/49(44.9%) had a central obesity.

Discussion

Current study showed that male who doing exercise 1-2 times weekly 44.83% less than non-doing as percentage 55.17% , regular exercise can lead to noticeable changes in BMI for overweight and obese people (1), Sherwood, 2001 are recommended the sport is in individual who are overweight and obese ,this type of sport is highly recommended (6).

It has been associated with increased symptoms of depression and anxiety in college students and adolescents(7).

As well as about (47.83%) from female do exercise 1-2 times weekly, while in male (44.83%) do exercise 1-2 times weekly, but this results disagreement with Hassan et al., who showed, only(1%)has a good level of daily physical activity , whilst 86.7% has low daily physical activity(8).

Man students had higher physical activity than women students, the results indicate that this variable is associated with BMI among man participants, While these aren’t the case with women, although it is believed that normal weight are more active than overweight or obese participants, whilst not the case with women, Although this is not the case in women, it is believed that normal weight are more active than obese participants (9).

So Otomo explained to lose weight, exercise more effective than other interventions(10). Proven aerobic weight loss(66.78)%, so percentage the Cholesterol as(27.67%) and fat(86.42%), therefore significant effect of low impact aerobics, weight loss, fat percentage and levels of cholesterol in women with obesity. This study also reveal that male (40%) doing exercise more than female (29%) and this is agree with another study occurred in Al-Najaf Al-Ashraf City(6).

Conclusion

- Most of the students have a normal BMI (55.56%) and a normal waist-to-height ratio (67.32).
- Among secondary school students (34%) only have regular exercise, from them (46.15%) doing exercise 1-2 times weekly.
